Introduction to Dummy Variables

◆□▶ ◆御▶ ◆臣▶ ◆臣▶ ―臣 … のへで

• Qualitative variables may be also important in explaining a dependent variable.

Quantitative:Income, Cost, Prices, Wages, ···Qualitative:Sex, Race, Religion, Geographic Region, ···

- How can we quantify these attributes?
- Use dummy variables (or indicator variables)
 - Example:

$$D_i = \begin{cases} 1 & \text{if the } i\text{-th person is female} \\ 0 & \text{if the } i\text{-th person is male} \end{cases}$$

<ロ> <四> <四> <四> <三</p>

One Dummy Variable

$$Y_i = \beta_1 + \beta_2 D_i + e_i$$

- Y_i: annual salary
- *D_i* takes a value of 1 for college graduates and 0 otherwise (non college graduates):

$$D_i = \begin{cases} 1 & \text{if college graduate} \\ 0 & \text{if non college graduate} \end{cases}$$

- What is the interpretation for dummy coefficient β_2 ?
 - $E[Y_i \mid D_i = 1] = \beta_1 + \beta_2$: Average salary of college graduates
 - $E[Y_i \mid D_i = 0] = \beta_1$: Average salary of non college graduates
 - Therefore, β_2 is difference in average salaries between two groups.

 $Y_i = \beta_1 + \beta_2 D_i + e_i$

- Note that we have two categories: college graduates and non college graduates
 - D_i takes a value 1 for college graduates \rightarrow Dummy variable is assigned for the category of college graduates.
 - The category for which no dummy variable is assigned is known as the benchmark category → Non college graduate is the benchmark category.
 - The intercept value (β_1) represents the mean value of the benchmark category.
 - The coefficients attached to the dummy variable (β₂) is known as differential intercept coefficient because they tell by how much the value of the category that receives the value of 1 differs from the intercept coefficient of the benchmark category.
- Regression models containing only dummy variables are called ANOVA (Analysis of Variance) models (because it analyzes variation between groups).

One Dummy Variable [cont'd]

$$Y_i = \beta_1 + \beta_2 D_i + e_i$$

• Estimation result:

$$\widehat{\text{salary}} = \underset{(57.74)}{18.0} + \underset{(7.44)}{3.28} D_i$$
(t-ratios in parentheses)

- Unit of Y : \$1,000
- Sample mean of salary of college graduates : $\hat{eta}_1+\hat{eta}_2=18.0+3.28=21.28$
- Sample mean of salary of non college graduates : $\hat{eta}_1 = 18.0$
- Estimated difference = 3.28
 - Consider H_0 : $\beta_2 = 0$ (v.s. H_1 : $\beta_2 > 0$) \Rightarrow We reject H_0 at 5% significance level.
 - College graduates receive significantly more salary on average than non college graduates!

Econometrics (Spring 2023)

Dummy Variable Regression Models

◆□▶ ◆御▶ ◆臣▶ ◆臣▶ ―臣 … のへで

- Let's continue to consider ANOVA models (salary and region).
- Suppose

- The qualitative variable "Region" has three categories.
- Choose the benchmark category: "Gyeonggi"
- We will introduce two dummies: D_{1i} , D_{2i}

Multiple Dummies: Example 1 [cont'd]

$$Y_i = \beta_1 + \beta_2 D_{1i} + \beta_3 D_{2i} + e_i$$

where

$$D_{1i} = \begin{cases} 1 & \text{if Seoul} \\ 0 & \text{otherwise} \end{cases}$$
$$D_{2i} = \begin{cases} 1 & \text{if Incheon} \\ 0 & \text{otherwise} \end{cases}$$

- β_1 : Average salary of persons living in Gyeonggi
- $\beta_1 + \beta_2$: Average salary of persons living in Seoul
- $\beta_1 + \beta_3$: Average salary of persons living in Incheon
 - How about $\beta_1 + \beta_2 + \beta_3$? \Rightarrow Not happens, because it is impossible to live in two regions at the same time.
- We can test $\beta_2 = 0$, $\beta_3 = 0$ to see if there are significant differences in salary across regions.

- Imagine we are interested in the effect of more than one qualitative variables on salary.
- Suppose now we want to see the effects of (a) region (Seoul or not), and
 (b) sex (male or female)

$$Seoul_i = egin{cases} 1 & ext{if person } i ext{ lives in Seoul} \ 0 & ext{otherwise} \ Male_i = egin{cases} 1 & ext{if person } i ext{ smale} \ 0 & ext{otherwise} \ \end{bmatrix}$$

$$Y_i = \beta_1 + \beta_2 Seoul_i + \beta_3 Male_i + e_i$$

- **9** β_1 (benchmark): Average salary of females living outside Seoul
- **2** $\beta_1 + \beta_2$: Average salary of females living in Seoul
- $\beta_1 + \beta_3$: Average salary of males living outside Seoul
- $\beta_1 + \beta_2 + \beta_3$: Average salary of males living in Seoul
 - Regional difference: $(2 1) = (4 3) = \beta_2$
 - Sexual difference: $(3 1) = (4 2) = \beta_3$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

One Dummy + One Quantitative Variable

$$Y_i = \beta_1 + \beta_2 D_i + \beta_3 X_i + e_i$$

- Y_i : annual salary of a teacher, X_i : years of experience
- D_i takes a value of 1 for male teachers and 0 for female teachers:

$$D_i = egin{cases} 1 & ext{if male} \ 0 & ext{if female} \end{cases}$$

- What is the interpretation for dummy coefficient β₂?
 - $E[Y_i \mid D_i = 1] = \beta_1 + \beta_2 + \beta_3 X_i$: Average salary of male teachers
 - $E[Y_i | D_i = 0] = \beta_1 + \beta_3 X_i$: Average salary of female teachers
 - β_2 is difference in average salaries between two groups, *controlling for* <u>experience years</u>.
- Regression models containing qualitative as well as quantitative variables are called ANCOVA (Analysis of Covariance) models.

One Dummy + One Quantitative Variable [cont'd]

• Estimation result:

$$\widehat{\text{salary}} = \underbrace{17.969}_{(93.61)} + \underbrace{3.3336}_{(38.45)} D_i + \underbrace{1.3707}_{(21.46)} X_i$$
(t-ratios in parentheses)

- Unit of Y : \$1,000
- $\hat{\beta}_3 = 1.3707$: On average, one additional year of experience increases teacher's salary by about 1.37 thousand dollars.
- $\hat{\beta}_2$ is the estimated differential intercept coefficient, controlling for X_i .
- Estimated difference = 3.3336
 - Is there sexual discrimination? *i.e.* Given the same experience, do male teachers earn more than female teachers on average?
 - Consider H_0 : $\beta_2 = 0$ (v.s. H_1 : $\beta_2 > 0$) \Rightarrow Reject H_0 .
 - ∴ Yes, there is sexual discrimination!

Dummy Variable Trap

◆□▶ ◆御▶ ◆臣▶ ◆臣▶ ―臣 … のへで

$$Y_i = \beta_1 + \beta_2 D_{1i} + \beta_3 D_{2i} + e_i$$

where

$$D_{1i} = \begin{cases} 1 & \text{if male} \\ 0 & \text{if female} \end{cases}$$
$$D_{2i} = \begin{cases} 1 & \text{if female} \\ 0 & \text{if male} \end{cases}$$

 In order to figure out the existence of sexual discrimination, you might want to test

$$H_0: \beta_2 = \beta_3 \quad v.s. \quad H_1: \beta_2 > \beta_3$$

2

- HOWEVER, the above model can't be estimated due to the problem of perfect multicollinearity!
 - We have $D_{1i} + D_{2i} = 1$, and 1 is the constant regressor.
- General rule: If a qualitative variable has m categories, introduce only (m-1) dummy variables.
 - For each qualitative regressor, the number of dummy variables introduced must be one less than the categories of that variable.
- If you do not follow this rule, you will fall into what is called the **dummy** variable trap.
- One way to circumvent this trap: If we do omit the intercept in the model, we can introduce as many dummy variables as the number of categories.
 - Caution: Make sure that when you run this regression, you use the no-intercept option in your regression package.

Application: Interaction Dummy

◆□▶ ◆御▶ ◆臣▶ ◆臣▶ ―臣 … のへで

Interaction Dummy

• Recall, Example 2 of salary with region and sex dummies.

 $Y_i = \beta_1 + \beta_2 Seoul_i + \beta_3 Male_i + e_i$

- **1** β_1 (benchmark): Average salary of females living outside Seoul
- 2 $\beta_1 + \beta_2$: Average salary of females living in Seoul
- **(a)** $\beta_1 + \beta_3$: Average salary of males living outside Seoul
- **(9)** $\beta_1 + \beta_2 + \beta_3$: Average salary of males living in Seoul
 - Implicit in this model is the assumption that the differential effect of the region dummy *Seoul*_i is **constant** across the two categories of sex, and the differential effect of the sex dummy *Female*_i is also **constant** across the regions.
 - If the mean salary is higher for Seoul residents, this is so whether they are male or not.
 - If the mean salary is higher for males than for females, this is so whether they live in Seoul or not.

- In many applications, such an assumption may be untenable.
 - A male Seoul resident may earn more wages than a male non-Seoul resident.
 - In other words, there may be interaction between the two qualitative variables *Seoul*_i and *Male*_i.

$$Y_i = \beta_1 + \beta_2 Seoul_i + \beta_3 Male_i + \beta_4 (Seoul_i \cdot Male_i) + e_i$$

- β_1 (benchmark): Average salary of females living outside Seoul
- **2** $\beta_1 + \beta_2$: Average salary of females living in Seoul
- $\beta_1 + \beta_3$: Average salary of males living outside Seoul
- $\beta_1 + \beta_2 + \beta_3 + \beta_4$: Average salary of males living in Seoul

- Now, the regional differences in two groups are not same!
 - Male wage difference between Seoul and non-Seoul = $(4 3) = \beta_2 + \beta_4$
 - Female wage difference between Seoul and non-Seoul = $@- @= \beta_2$
- Is there more regional difference (Seoul vs. non-Seoul) among males than among females?

• Test
$$H_0: \beta_4 = 0$$
 vs. $H_1: \beta_4 > 0$

<ロ> <四> <四> <四> <三</p>

Slope Dummy

- One can interact dummy variables with other quantitative regressors.
- Consider the following model:

$$Y_i = \beta_1 + \beta_2 X_i + \beta_3 \left(D_i X_i \right) + e_i$$

- D_i is a dummy variable and X_i is a quantitative variable.
- $D_i X_i$ is the product of a dummy variable and a (quantitative) regressor, called a slope dummy because it allows for a change in the slope of relationship.

$$E(Y_i) = \begin{cases} \beta_1 + (\beta_2 + \beta_3) X_i & \text{when } D_i = 1\\ \beta_1 + \beta_2 X_i & \text{when } D_i = 0 \end{cases}$$
$$\implies \frac{\partial E(Y_i)}{\partial X_i} = \begin{cases} \beta_2 + \beta_3 & \text{when } D_i = 1\\ \beta_2 & \text{when } D_i = 0 \end{cases}$$

$$Y_i = \beta_1 + \beta_2 X_i + \beta_3 \left(D_i X_i \right) + e_i$$

- **Example:** Y_i = house price, X_i = size of house (in square feet), $D_i = 1$ if the house is in the desirable neighborhoods, $D_i = 0$ if the house is in other neighborhoods.
- $D_i X_i$: Indicates the interaction effect of location and size on house price
- Interpretation
 - In the desirable neighborhoods, as the house size goes up by 1 square feet, the house price goes up by $\beta_2 + \beta_3$.
 - In other neighborhoods, the effect of house size on prices is β_2 .
